Clone the Wikipedia app from Github (https://github.com/wikimedia/wikipedia-ios)

The app can be called from other apps via deep linking.

Modify the Wikipedia app so that it can be called in a way so that, when started, it directly goes to the Places tab and shows the location specified by the calling app (e.g. via coordinates), instead of the current location.

Create a simple test app with a list of locations. Tapping on a location should call the Wikipedia app in this new way to demonstrate the functionality.
The user of the test app should be allowed to enter a custom location and open the wikipedia app there.

Work locally and perform your changes locally (but still using git). Once done, zip the entire repo folder (including the .git subfolder) and send a link to me (caleb.repkes@nl.abnamro.com). You can use a service like WeTransfer or similar for that.

No existing functionality should otherwise be altered.
